**Abstract** Binary and ternary platinum(II) and platinum(IV) complexes were synthesized using heterocyclic ligands with nitrogen and oxygen donor atoms (2-pyrazinecarboxamide, pyridine, and bipyridine). The complexes were characterized by the analytical and spectroscopic tools such as elemental analysis, mass spectrometry, IR, and <sup>1</sup>H NMR spectroscopy. The complexes showed different structural arrangements. The thermogravimetry analysis of some selected complexes were also investigated. Theoretical calculations based on accurate density functional theory (DFT) approximations were established to verify the optimized structures of the pyrazine carboxamide ligand and two complexes. The global chemical reactivity descriptors were estimated from the energy of the HOMO and LUMO orbitals.

**Keywords** pyrazine derivatives; platinum complexes; spectroscopic studies; DFT studies

## 1. Introduction

Transition metal-based complexes represent an important class of chemotherapeutics, widely used in the clinic as antitumor and antiviral agents. They offer potential advantages over the more common organic-based drugs. The more established antitumor metallodrugs, routinely used in treatment of cancer patients, are *cis*-platin [*cis*-diamminedichloroplatinum(II)] and its analogues [1]. However, their drug resistance and side effects have limited their clinical use. Vast efforts are committed to develop novel transition metal-based derivatives, such as platinum(II), platinum(IV) and ruthenium complexes, which might overcome the disadvantages of *cis*-platin and have higher antitumor activity as well [2,3,4,5]. Considerable amount of interest has focused on the use of pyridine platinum(II) complexes as mimics of *cis*-platin [6]. These studies have shown that the use of planar ligands, such as the substituted pyridines in platinum(II) complexes, can reduce the rate of deactivation by sulfhydryl groups without interfering with DNA binding, which is considered to be the mode of action of *cis*-platin [6,7,8].

Our interest in the synthesis of various transition metal complexes with heterocyclic ligands that have appropriate

**Scheme 1:** Structure of ligands.

biological activities and show promising applications as antitumor drugs [3,4] has prompted us to synthesize and investigate other platinum(II) and platinum(IV) complexes of these ligands (Scheme 1). In this article, we report the synthesis, and characterization of some Pt(II) and Pt(IV) complexes with nitrogen heterocyclic ligands. Density functional theory (DFT) calculations are also carried out to explore the optimized structures of the ligand and some complexes.

## 2. Experimental methods

### 2.1. Materials and instruments

Chloride salts of platinum(II) and platinum(IV), in addition to the heterocyclic nitrogen donor ligands, were purchased from Aldrich. All the solvents were of analytical reagent grade and were purified using standard methods. IR measurements (KBr pellets) were carried out on a Unicam-Mattson 1000 FT-IR spectrometer.

**Table 1:** Color, yield, elemental analysis, and mass spectrometry data of the platinum complexes.

NMR measurements were performed on a Spectrospin-Bruker 300 MHz spectrometer. Thermogravimetric analysis measurements were carried out (N<sub>2</sub> atmosphere) at a heating rate of 10 °C/min using a Shimadzu DT-50 thermal instrument. Elemental analyses were measured using Perkin-Elmer 2400 CHN elemental analyzer. Mass spectrometry measurements of the solid complexes (70 eV, EI) were carried out on a Finnigan MAT SSQ 7000 spectrometer. Conductivity measurements were made on a YSI conductivity meter model 32. Samples of concentration ca.  $1 \times 10^{-3} - 1 \times 10^{-6}$  M in DMSO were used for the measurements.

## 2.2. Synthesis of complexes

### 2.2.1. Synthesis of [Pt(PCA)<sub>2</sub>]Cl<sub>2</sub> complex

A solution of pyrazine carboxamide (PCA) ligand (0.5 mmol) in a minimum amount of ethanol is added dropwise with constant stirring to a 0.5 mmol solution of [PtCl<sub>4</sub>]<sup>2-</sup>. The mixture was heated for half an hour at 60 °C, at which the complex was precipitated. The resultant residue was filtered off and washed with hot petroleum ether. The obtained residue was recrystallized from hot ethanol. The isolated fine crystals were left to dry under vacuum for several hours.

### 2.2.2. Synthesis of ternary Pt(II) and Pt(IV) complexes

Equimolar amounts of the PCA ligand with either pyridine or bipyridine (0.5 mmol from each) were mixed and dissolved in the minimum amount of ethanol. The solution was added dropwise with constant stirring to an aqueous solution of [PtCl<sub>4</sub>]<sup>2-</sup> or [PtCl<sub>6</sub>]<sup>2-</sup> (0.5 mmol). The mixture was heated to 70 °C for 1 h. The solvent was evaporated, and the solid residue was washed with hot petroleum ether and then recrystallized from hot ethanol. The isolated fine crystals were left to dry under vacuum for several hours.

## 2.3. Computational details

All the calculations were performed using the hybrid DFT method B3LYP as implemented in the Gaussian 09 software package. The geometries were optimized using the standard double-zeta plus polarization basis set 6-31G (d,p) for PCA ligand atoms and effective core potential basis set LANL2DZ for platinum complexes. The purpose of the quantum mechanics calculations validates the proposed 3D structure of the obtained complexes so as to find out key factors for their reactivities.

## 3. Results and discussion

### 3.1. Spectroscopic and analytical studies

Some platinum(II) and platinum(IV) complexes were isolated from the reactions of 2-pyrazinecarboxamide (PCA) and a secondary ligand (either pyridine, Py, or bipyridine, Bpy). The chemical composition of these complexes was as follows: [Pt(PCA)<sub>2</sub>]Cl<sub>2</sub> (1), [Pt(PCA)(Py)<sub>2</sub>]Cl<sub>2</sub> (2), [Pt(PCA)(Bpy)]Cl<sub>2</sub> (3), [Pt(PCA)(Py)<sub>2</sub>Cl<sub>2</sub>]Cl<sub>2</sub> (4), [Pt(PCA)(Bpy)Cl<sub>2</sub>]Cl<sub>2</sub> (5). The structures of the complexes were characterized using elemental analysis, mass, IR, <sup>1</sup>H NMR spectrometry as well as thermogravimetry (TG) technique. The ionized and total chloride contents of the complexes were determined potentiometrically using silver ion electrode. Table 1 gives the color, yield, elemental analysis, and mass spectrometry data of the complexes. The fragmentation patterns in the mass spectra of the complexes along with the thermal analysis as well as the elemental analysis data revealed the correctness of the suggested molecular formulas. The electrical molar conductance in DMSO at room temperature for all complexes exhibited high molar conductance (112.5–136.4 μS) due to their electrolytic characteristics and the number of ionized chloride ions.

The IR spectra of the complexes displayed characteristic bands of ligands,  $\nu(\text{NH})$ ,  $\nu(\text{C}=\text{N})$ , and  $\nu(\text{C}=\text{O})$ , with

**Table 2:** IR and NMR data of the PCA and the platinum complexes.

Compound	IR data (cm <sup>-1</sup> )			<sup>1</sup> H NMR data (ppm)

[Pt(PCA)(Py) <sub>2</sub> Cl <sub>2</sub> ]Cl <sub>2</sub> (4)	3,266 (m) 3,188 (m) 3,100 (m) 3,068 (m)	1,650 (m) 1,592 (m)	1,712 (s)	9.23 (d, 1 Hz, Pz-CH), 8.95 (m, Py-CH), 8.86 (d, 8 Hz, Pz-CH), 8.76 (dd, 9, 1 Hz, Pz-CH), 8.24 (bs, NH), 8.09 (m, Py-CH), 7.93 (bs, NH), 7.71 (m, Py-CH), 7.58 (m, Py-CH)
[Pt(PCA)(Bpy)Cl <sub>2</sub> ]Cl <sub>2</sub> (5)	3,265 (m) 3,192 (m) 3,103 (m) 3,064 (m)	1,644 (m) 1,590 (m)	1,700 (s)	9.52 (d, 1 Hz, Pz-CH), 9.21 (d, 8 Hz, Pz-CH), 8.87 (m, Py-CH), 8.71 (dd, 7, 1 Hz, Pz-CH), 8.53 (bs, NH), 8.44 (m, Py-CH), 8.32 (bs, NH), 7.84 (m, Py-CH)

corresponding shifts due to complex formation (Table 2) [3, 9,10]. The stretching frequencies of C=N bonds in the IR spectra of complexes were shifted to higher frequencies, while the  $\nu(\text{NH})$  in complexes containing 2-pyrazinecarboxamide ligand were shifted to lower frequencies relative to those of free ligand [11,12,13]. The  $\nu(\text{C}=\text{O})$  frequencies were shifted to lower frequencies confirming participation of the carbonyl group of the PCA in coordination of their complexes [10]. Furthermore, all the spectra showed nonligand bands in the range 651–419 cm<sup>-1</sup> corresponding to the stretching frequencies of M–O and M–N bonds [10,11,14,15].

The <sup>1</sup>H NMR spectra of the complexes gave more insight on their structure. All the spectra performed signals due to protons of the coordinated ligands. The spectra of the ternary complexes showed signals due to the NH, pyridyl, and pyrazine moieties with corresponding shifts (Table 2) [13,16]. From the spectroscopic data, it can be concluded that the 2-pyrazinecarboxamide and bipyridine acted as bidentate through nitrogen and oxygen donor atoms, while the pyridine ligand coordinated from the pyridyl nitrogen (Scheme 2).

### 3.2. Thermal analysis

To examine the structure and thermal stability of the platinum complexes, thermal studies were carried out

**Scheme 2:** The proposed structure of the complexes.

using thermogravimetry (TG) technique [17]. The TG data of the complexes are tabulated in Table 3. The TG curve of [Pt(PCA)(Py)<sub>2</sub>]Cl<sub>2</sub> (2) complex exhibited two

**Table 3:** Thermal analysis data for the platinum complexes.

Molecular formula	Molecular weight	Decomposition temperature (°C)	Weight loss (%)	Mass loss/mole found (Calc.)	Eliminated species	Solid decomposition residue (%)
[Pt(PCA)(Py) <sub>2</sub> Cl <sub>2</sub> ] (2)	547.41	77–406	34.65	189.68(190.13)	C <sub>7</sub> H <sub>6</sub> + N <sub>2</sub> + Cl <sub>2</sub>	38.53
		407–649	26.63	145.77 (149.16)	C <sub>8</sub> H <sub>9</sub> + N <sub>2</sub> + 0.5O <sub>2</sub>	(Pt)
[Pt(PCA)(Bpy)]Cl <sub>2</sub> (3)	545.29	50–277	7.70	42.00 (42.00)	CO + 0.5N <sub>2</sub>	38.95
		279–413	24.30	132.32 (143.04)	CH <sub>4</sub> + 2N <sub>2</sub> + Cl <sub>2</sub>	
		414–565	29.00	158.15 (153.20)	C <sub>12</sub> H <sub>9</sub>	(PtC <sub>2</sub> )

**Figure 1:** The optimized structures of PCA and platinum complexes.

well-defined decomposition steps within the temperature range 77–649 °C. The first decomposition step occurred at temperature range 77–406 °C and was corresponding probably due to the loss of C<sub>7</sub>H<sub>6</sub> + N<sub>2</sub> + Cl<sub>2</sub> species. The second decomposition step included the removal of C<sub>8</sub>H<sub>9</sub> + N<sub>2</sub>O with a net weight loss of 26.63% leaving metallic platinum as a residue.

The thermogravimetric plot of the [Pt(PCA)(Bpy)]Cl<sub>2</sub> (3) complex showed three well-defined decomposition steps within the temperature range 50–565 °C. The first decomposition step corresponded to the loss of CO + 0.5N<sub>2</sub> moieties with a net weight loss of 7.70%. The second decomposition step within the temperature range 279–413 °C (net weight loss of 24.30%) was assigned to the elimination of CH<sub>4</sub> +

2N<sub>2</sub> + Cl<sub>2</sub> species. The third decomposition step within the temperature range 414–565 °C gave mass loss of 29.00% (Calc. 28.09%) assigned to the elimination of C<sub>12</sub>H<sub>9</sub> moiety to give finally PtC<sub>2</sub> species as a residue.

According to the thermogravimetric patterns of the investigated complexes, the thermal stability increases in the order [Pt(PCA)(Bpy)]Cl<sub>2</sub> < [Pt(PCA)(Py)<sub>2</sub>]Cl<sub>2</sub>.

### 3.3. The stereochemistry and chemical reactivity prediction

The stereochemistry of PCA and two of the platinum complexes were investigated by the hybrid DFT method. The optimized structures of these compounds are given in Figure 1. We will focus first on the structure of the PCA with a total steric energy = 5.34 kcal/mol. The dihedral angle

**Figure 2:** The frontier molecular orbitals of PCA and the platinum complexes.

between the two planes including  $C_1-C_2-C_{10}-N_{11}$  was found to be  $33.6^\circ$ , which means that the molecule is almost planar. The bond lengths between  $C_{10}-O_{14}$  and  $C_{10}-N_{11}$ , Figure 1, were 1.22 Å and 1.38 Å, respectively. These values are in the expected range of  $C=O$  and  $C-N$  [18, 19]. On the other hand, the bond angle of  $C_2-C_{10}-N_{11}$  is found to be smaller ( $114.64^\circ$ ) than that of  $C_2-C_{10}-O_{14}$ ,  $122.2^\circ$ . This could retain to the repulsion of the two lone pairs on the oxygen atom.

The energetically stable model of  $[Pt(PCA)_2]^{2+}$  (1) species with a distorted square planar geometry was found to have about 77.51 kcal/mol, which is consistent with the spectroscopic findings (Scheme 1). The bond angles  $N_9-Pt_{24}-O_{25}$ ,  $N_{12}-Pt_{24}-O_{23}$ , and  $O_{23}-Pt_{24}-O_{25}$  were found to be  $79.0^\circ$ ,  $79.0^\circ$ , and  $92.0^\circ$ , respectively. Again, the larger value of the latter bond could be due to the oxygen lone pair repulsion. On the other hand, the bond angles of  $N_{12}-Pt_{24}-O_{25}$  and  $N_9-Pt_{24}-O_{23}$  are close to linear

( $170.1^\circ$ ). The  $Pt-N$  (2.06 Å) bond length was found to be slightly longer than that of  $Pt-O$  (2.03 Å). In case of the  $[Pt(PCA)(Bpy)]^{2+}$  (3) complex, the optimized structure has a minimization energy of 79.80 kcal/mol with a distorted square planar structure (Figure 1). The bond lengths and bond angles were found to be comparable with those of the complex (1). Selected values are  $N_{19}-Pt_{35}$  (2.02 Å),  $O_{34}-Pt_{35}$  (2.07 Å),  $C_{30}-O_{34}$  (1.30 Å),  $N_{19}-Pt_{35}-N_{20}$  ( $79.9^\circ$ ),  $N_{23}-Pt_{35}-O_{34}$  ( $78.2^\circ$ ), and  $N_{19}-Pt_{35}-N_{23}$  ( $170.4^\circ$ ), respectively.

The global chemical reactivity parameters including HOMO, LUMO, energy gap ( $\Delta E$ ), electronegativity ( $X$ ), chemical potential ( $V$ ), electron affinity ( $A$ ), ionization potential ( $I$ ), chemical hardness ( $\eta$ ), chemical softness ( $S$ ), and electrophilicity ( $\omega$ ) of the reported compounds are given in Table 4 [20, 21, 22, 23]. The frontier molecular orbital energies were estimated using DFT method (B3LYP) and illustrated in Figure 2. The HOMO orbital energy

**Table 4:** The global chemical reactivity descriptors for the PCA and the platinum complexes.

Parameter	PCA	1	3
DM (Debye)	3.39	0.20	0.68
HOMO (eV)	−6.80	−14.37	−13.60
LUMO (eV)	−1.82	−10.47	−9.94
ΔE (eV)	4.98	3.90	3.66
X (eV)	4.31	12.42	11.77
V (eV)	−4.31	−12.42	−11.77
A (eV)	1.82	10.47	9.94
I (eV)	6.80	14.37	13.60
η (eV)	2.49	1.95	1.83
S (eV)	1.24	0.98	0.92
ω (eV)	3.73	39.50	37.84

represents the electron donating ability, while the LUMO orbital energy characterizes the electron withdrawing ability. The energy gap between HOMO and LUMO shows the molecular chemical stability; it is a critical parameter for determining molecular electrical transport properties. Smaller energy gap reflects the easiness of the charge transfer (CT), and the polarization which occurs within the molecule [24]. Therefore, the order of increasing reactivity of the reported complexes is  $[\text{Pt}(\text{PCA})(\text{Bpy})]^{2+} > [\text{Pt}(\text{PCA})_2]^{2+}$ . Also, the electronegativity parameter is a reflection for the electrostatic potential, where the electron partially transferred from one of lower electronegativity to another of higher electronegativity [24]. The results showed that the order of decreasing  $X$  is  $[\text{Pt}(\text{PCA})_2]^{2+} > [\text{Pt}(\text{PCA})(\text{Bpy})]^{2+}$ . On the other hand, the results of small chemical hardness values for the reported derivatives reflect the ability of charge transfer within the molecule. The order of increasing the charge transfer within the molecule is  $[\text{Pt}(\text{PCA})_2]^{2+} < [\text{Pt}(\text{PCA})(\text{Bpy})]^{2+}$ .

#### 4. Conclusion

Spectroscopic studies of some binary and ternary Pt(II) and Pt(IV) complexes of heterocyclic ligands showed variable molecular and structural features. Optimized structures of the ligand and some platinum complexes using DFT calculations revealed the correctness of the proposed structures.
